

# FUNGI FOR CLEANING-UP OIL SPILLS AND OTHER CONTAMINATED SITES

Lara Valentín Carrera

MUTKU Päivät

Hämeenlinna, 31<sup>st</sup> March 2011

# CASE 1: OIL SPILLS

- Sustainable technology
- Litter-decomposing
- White-rot fungi
- Contamination
- Soil

GREENPEACE

On 19<sup>th</sup> November 2002, the single-hulled oil tanker Prestige sank on the Cap Finisterre (NW Spain)

- Sustainable technology
- Inter-depositing
- White-rot fungi
- Contamination
- Oil
- PAHs

- Spilled quantity on the sea: 64000 tons of heavy fuel oil (N°2 M100).
- Affected coastal area : 1900 km of estuaries, marshes, beaches, etc.
- Affected countries: Spain, Portugal, France, England.
- 16000 - 23000 tons still on the ship (Science 22, 2006).
- Risk of biocorrosion.

An important fraction of the Prestige oil consists of Polycyclic Aromatic Hydrocarbons (PAHs)

- Due to their low solubility, PAHs are mainly deposited into sediments or coastal areas.

- Toxic: PAHs are associated with lung and bladder cancers.

- More benzene rings:
  - Higher carcinogenicity risk.
  - Lower solubility.
  - Lower bioavailability.
  - More resistant to bacterial degradation.

- Sustainable technology
- Litter-decomposing white rot fungi
- Contamination
- Soil
- PAHs

## CASE 2: CONTAMINATED SAWMILL SOIL

- Sustainable technol
- Litter-decomposing
- White-rot fungi
- Contamination
- Soil

1940 – 1984, Finland: Around 23400 tons of chlorinated wood preservatives (KY-5) were produced.

- 550 (former) wood preservation and sawmill sites potentially contaminated → 100 requiring urgent treatment.
- Highly contaminated sites → excavation + combustion(>1300°C).
- High soil organic matter.
- Limitations:
  - decrease combustion process capacity.
  - longer treatment time.
  - more fuel.

- Sustainable technology
- Litter decomposition
- White-rot fungi
- Contamination
- Soil
- PAHs

*Ex situ* bioremediation technologies to clean-up PAHs contaminated salt marsh soil and pre-treat sawmill soil.

Bioremediation technologies

Monitored Natural Attenuation

*In situ*

- Biostimulation
- Bioaugmentation

*Ex situ/on site*

- Composting
- Bioreactor
- Biopiles

- Sustainable technology
- Litter-decomposing
- White-rot Fungi
- Contamination
- Soil PAHs

*Bjerkandera adusta* (WRF)

*Gymnopilus penetrans* (LDF)

*Irpex lacteus* (WRF)

# Fungi with most potential to degrade contaminants are wood-degrading Basidiomycetes

- White-rot fungi (WRF) live in standing or fallen dead wood (hardwoods; beech, birch). Degrade lignin, hemicellulose and cellulose from wood cells.

- Litter-decomposing fungi (LDF) live in the upper layer of the soil. Decompose dead leaves, needles, branches, roots causing white-rot to soil-litter.

- Fungi whose habitat is wood in direct contact with the soil (e.g. *Hypholoma* spp.).

- Sustainable technology
- Litter-decomposing
- White-rot fungi
- Contamination
- PAHs

# Why these fungi can be used for bioremediation applications?

- Production of mycelium spreading upon the soil.

- Non-specific and extracellular lignin-modifying enzymes
  - Lignin Peroxidase
  - Manganese Peroxidase
  - Laccase

- Tolerate organic contaminants and heavy metals.

- Lignocellulosic material as substrate for fungi (e.g. wood chips, bark, straw, etc)

- Sustainable technology
- Litter-decomposing white-rot fungi
- Contamination
- Soil
- PAHs

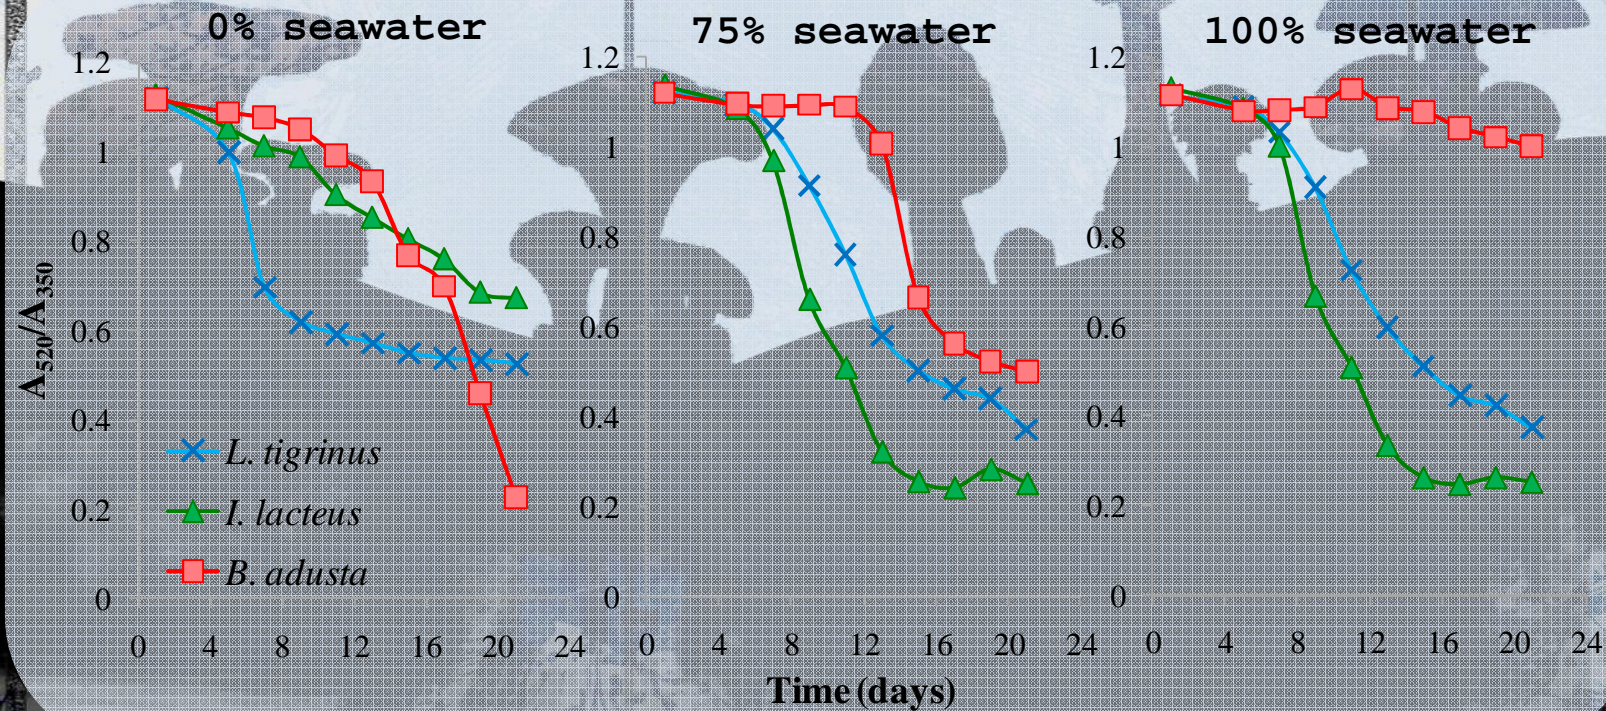

# Case 1: FUNGAL DEGRADATION OF PAHS FROM SALT MARSH SOIL IN A SLURRY BIOREACTOR

- Sustainable technology
- Litter-decomposing
- White rot fungi
- Contamination
- Soil
- PAHs

After the screening of PAH degradation in small slurry reactors with 9 fungi, the effect of seawater on the enzymatic system of 3 fungi was evaluated

$A_{520}/A_{350}$  is the absorbance rate of the Polyaromatic Hydrocarbons

# PAH degradation in 5 L bioreactor operated with *Bjerkandera adusta*

PAHs = dibenzothiophene, fluoranthene, pyrene and chrysene

- Sustainable technology
- Litter-decomposing
- White-rot fungi
- Contamination
- Soil
- PAHs

- Sustainable technology
- Litter-decomposing
- White-rot fungi
- Contamination
- Soil
- PAHs

Similar fermentation  
profile of *Bjerkandera*  
in a marsh soil  
surrey and  
contamination

## Conclusions case 1

- Sustainable technol
- Litter-decomposing
- White-rot fungi
- Contamination
- Soil
- PAHs

- Several white-rot fungi (WRF) are halotolerant (tolerate salt) and are able to degrade PAHs under slurry conditions: *Bjerkandera adusta*, *Irpex lacteus* and *Lentinus tigrinus*.
- The process was successfully scaled-up (5 L) using *B. adusta* as free mycelium.
- Fungus and soil endogenous microbes cooperate in the degradation of PAHs.

## CASE 2: FUNGAL SOLID PHASE PRE-TREATMENT OF CONTAMINATED SOIL TO DECREASE ORGANIC MATTER CONTENT

- Sustainable technology
- Litter decomposition
- Contamination
- Soil

# Screening of 146 wood-degrading fungi in contaminated sawmill soil resulted in the selection of 18 fungi

- Sustainable technology
- Waste-decomposing
- White-rot fungi
- Contamination
- Soil
- PAHs

Manganese peroxidase activity (mU/g of dry bark)

# Degradation of organic matter from contaminated sawmill soil by fungi

2.1 mg/kg I-TEQ PCDD/Fs; 500 ml bottles; bark:soil = 21:100 (w/w)

Initial soil organic matter (OM) was 84%

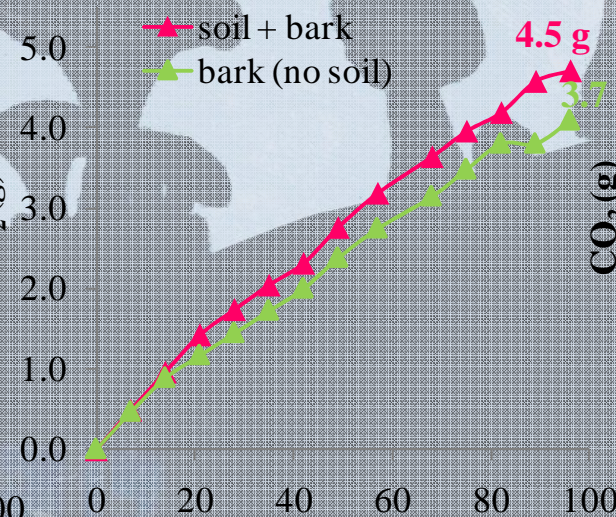

- Sustainable technology
- Litter-decomposing white-rot fungi
- Contamination
- PAHs

Respiration of *P. velutina*

C loss = 3.4%  
OM (6 months) = 79%

Respiration of *S. rugosannulata*

C loss = 2.4%  
OM (6 months) = 80%

Respiration of *G. luteofolius*

C loss = 1.8%  
OM (6 months) = 81%

# Scale-up of the fungal pre-treatment process

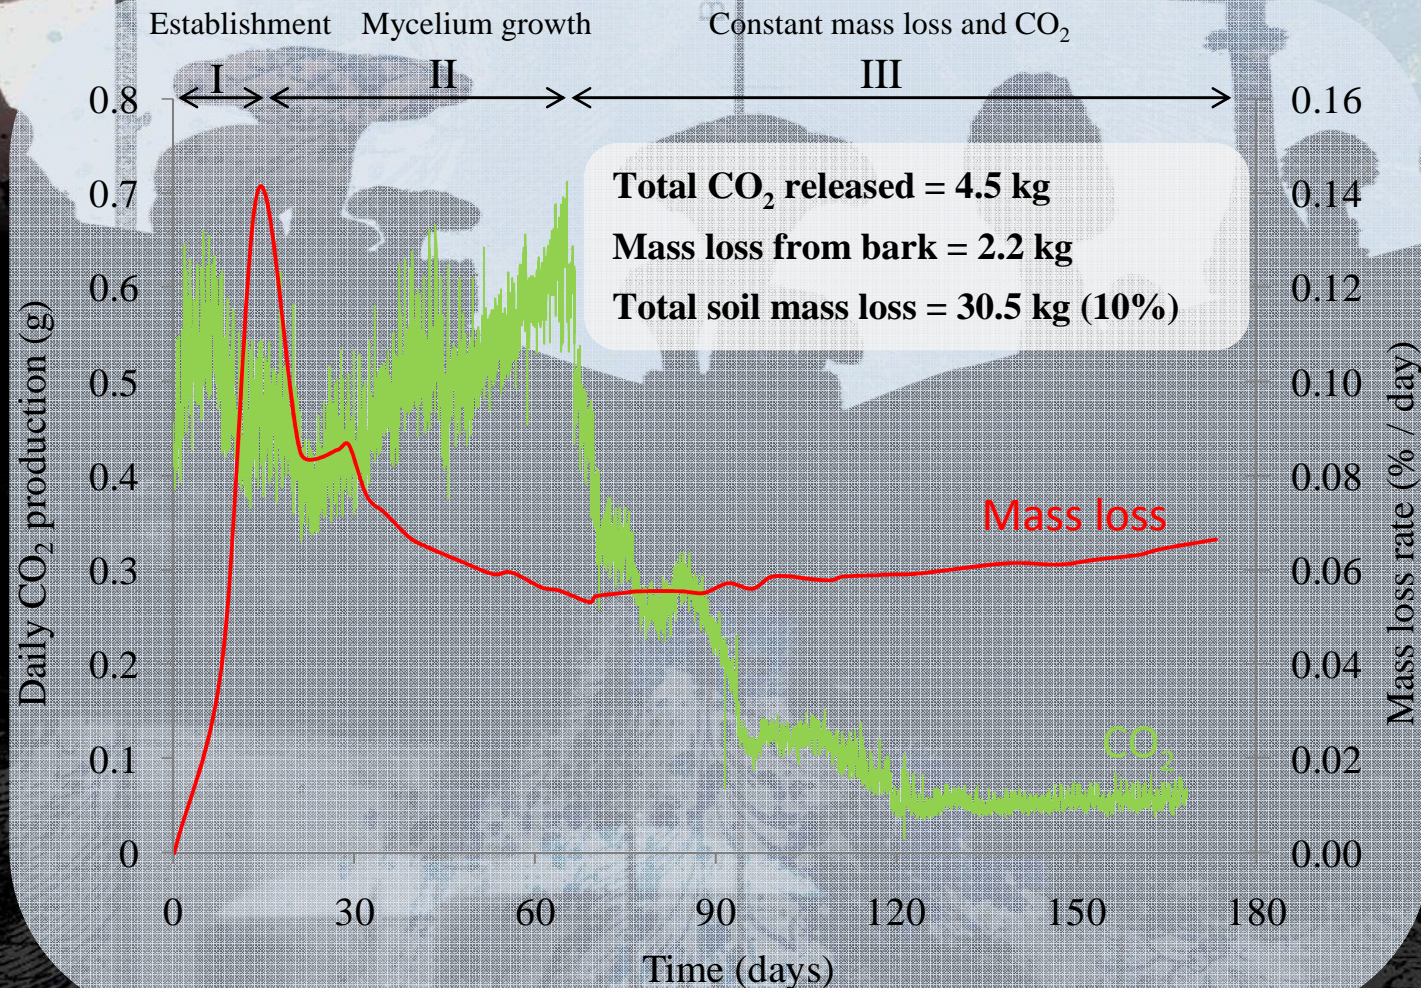

Biopile 0.56 m<sup>3</sup>; 308 kg of contaminated sawmill soil

82% OM; 0.07 mg/kg I-TEQ PCDD/Fs

Fungal-bark inocula in 6 mesh tubes (1.5 kg bark in each tube)

*Stropharia rugosoannulata*

- Sustainable technology
- Waste processing
- White-rot fungi
- Contamination
- Soil
- PAHs

Set-up biopile

Fungal-bark tube

Mycelium in wood (6 months)

## Conclusions case 2

- Sustainable technol
- Litter-decomposing
- White-rot fungi
- Contamination
- Soil
- PAHs

- Litter-decomposing fungi (LDF) are the most outstanding colonizers of contaminated soil.
- Manganese peroxidase and endo-1,4- $\beta$ -glucanase are the main enzymes produced by fungi in bark and soil.
- White-rot fungi and LDF are able to degrade soil organic matter during a pretreatment process using pine bark as substrate.
- Scots pine bark promotes fungal growth and production of extracellular enzymes (MnP).

# POTENTIAL FULL-SCALE APPLICATION (*in situ* OR *ex situ*)

- Sustainable technology
- In-situ-decomposing
- White-rot fungi
- Contamination
- Soil
- PAHs

Illustration by R. Valentin

# POTENTIAL FULL-SCALE APPLICATION

## Production of fungal inocula

- Sustainable technology
- White-rot-decomposing fungi
- Contamination
- Soil
- PAHs

1<sup>st</sup> step: Production of liquid inocula in continuous stirred tank reactor (CSTR).

2<sup>nd</sup> step: Production of fungal inocula in lignocellulosic substrate (bark) in aerated and step sterilized static chambers.

Lignocellulosic substrate inoculated with homogenized mycelia

# POTENTIAL FULL-SCALE APPLICATION

## Introduction of fungal inocula into soil

Perforated tubes filled with fungus  
growing on selected lignocellulosic substrate

- Sustainable technology
- Faster-decomposing
- White-rot fungi
- Contamination
- Soil
- PAHs
